TABLES AND GRAPHS OF THE THEORETICAL PEAK PRESSURES, ENERGIES,
AND POSITIVE IMPULSES OF BLAST WAVES IN AIR

Abstract

A theory of the propagation of shock waves from explosive sources was presented in OSRD Report No. 4814. In that report, a pair of ordinary differential equations for peak pressure and shock-wave energy as functions of the distance from the source were formulated from the equations of hydrodynamics by imposing a similarity restraint on the shape of the energy-time curve of the shock wave. Two-parameter families of peak pressure-distance, shock-wave energy-distance, and positive impulse-distance curves are obtained by the solution of these propagation equations. The parameters are conveniently chosen as the initial values of the pressure and shock-wave energy.

In the present report, tables and graphs of the two-parameter families of curves for blast waves from explosive sources in air are presented. A method is outlined for the determination of the parameters from experimental values of the peak pressure and positive impulse over a limited range of distances from the source. Estimates of the properties of the blast wave produced by TNT are obtained in this manner, and tentative peak pressure-distance and impulse-distance curves for all distances from the charge are constructed.

I. DESCRIPTION OF THE TABLES AND GRAPHS OF THE PROPERTIES OF
BLAST WAVES IN AIR

1. Introduction

A theory of propagation of shock waves from explosive sources has been described in an earlier report.^{1/} A pair of ordinary differential equations for peak pressure and shock-wave energy as functions of distance from the source were obtained from the equations of hydrodynamics and the Hugoniot relations by imposing a similarity restraint on the shape of the energy-time curve and by utilizing the second law of thermodynamics to determine, at an arbitrary distance, the distribution of the initial energy input from the explosive between energy available for further propagation and dissipated energy residual in the fluid already traversed by the shock wave. The theory takes

^{1/} Theory of the propagation of shock waves from explosive sources in air and water, by J. G. Kirkwood and S. R. Brinkley, Jr., NDRC Report A-318 (OSRD-4814).

proper account of the finite entropy increment in the fluid resulting from the passage of the shock wave and permits the use of the exact Hugoniot curve for the fluid.

The basic equations of the theory are

$$\left. \begin{aligned} \frac{dp}{dR} + \frac{p}{R} n(p) &= -\left(1 - \frac{1}{3} e^{-p}\right) \frac{R^2 p^4}{K} F(p), \\ \frac{dK}{dR} &= -p^3 R^2 f(p), \end{aligned} \right\} \quad (1)$$

where

$$f(p) = \frac{12 \gamma^3}{\gamma + 1} \frac{h}{c_0^2 p^3},$$

$$F(p) = \frac{12G}{p} \frac{\gamma}{\gamma + 1} \left(\frac{c_0}{U}\right)^2 \frac{1}{2(1 + g) - G},$$

$$n(p) = \frac{4(\rho_0/\rho) + 2(1 - \rho_0/\rho)G}{2(1 + g) - G},$$

$$G = 1 - \left(\frac{\rho_0 U}{\rho c}\right)^2, \quad g = 1 - \frac{p}{U} \frac{du}{dp},$$

and p is the excess peak pressure measured in units of the pressure p_0 of the undisturbed air ahead of the shock wave, at a distance R_{a_0} from the center of a spherical charge of explosive of radius a_0 . The quantities ρ and ρ_0 are the densities of the air at distances R and infinity, respectively, c and c_0 denote the sound velocity in air at densities ρ and ρ_0 , respectively, U is the velocity of the shock front, and γ is the ratio of the heat capacities of air at a pressure p_0 and temperature of $300^\circ K$, h is the specific enthalpy increment of an element of fluid, traversed by a shock wave of peak pressure p , after return to pressure p_0 along its new adiabatic. The variable K is related to the shock-wave energy ϵ per gram of the initial explosive charge by

$$\epsilon = \frac{\gamma + 1}{4\gamma^2} \frac{p_0}{\rho_e} K, \quad (2)$$

where ρ_e is the density of loading of the explosive. The positive impulse is given by

$$I = \left(1 - \frac{1}{2} e^{-\sqrt{p}}\right) \frac{p_0 \rho a_0}{c_0} \left\{ \frac{1}{R} \alpha(p) + \frac{R^2}{K} \beta(p) \right\}^{-1}, \quad (3)$$

where

$$\alpha(p) = 2 \frac{U}{c_0} \left\{ \left(\frac{\rho}{\rho_0} - 1 \right) \left[\frac{1 + g - (1 - \rho_0/\rho)G}{2(1 + g) - G} \right] + \frac{2(\rho_0/\rho) - 1}{2(1 + g) - G} \right\},$$

$$\beta(p) = \frac{12\gamma}{\gamma+1} \left(1 - \frac{1}{3} e^{-p} \right) \frac{p^2 (\rho/\rho_0)}{(U/c_0)} \left\{ \frac{1 + g - (1 - \rho_0/\rho)G}{2(1 + g) - G} \right\}.$$

Tables of functions which are closely related to those defined in Eqs. (1) and (3) have been presented in the earlier report.^{1/}

2. Description of the tables and graphs

The two-parameter family of peak pressure-distance curves and the family of shock-wave energy-distance curves for selected values of the constants of integration were obtained by numerical integration of Eqs. (1), employing the methods of Part III of the previous report.^{1/} Each member of the two families is characterized by a value of p_1 , the excess peak pressure at the initial instant of time measured in units of ρ_0 , and by a value of Q_1 , related to the initial shock-wave energy ϵ_1 by

$$Q_1 = \frac{4\gamma^2}{\gamma+1} \frac{\rho_e \epsilon_1}{p_0 p_1}. \quad (4)$$

The family of peak pressure-distance curves is presented in tabular form in Table I. In this and following tables, a reduced distance variable equal to $R(\rho_e/W)^{1/3}$ is employed, where R is expressed in feet, ρ_e in grams per cubic centimeter, and W in pounds. In order to facilitate interpolation with respect to distance, the entries of the table are of the function $pR(\rho_e/W)^{1/3}$ with p expressed in pounds per square inch.^{2/}

Portions of the peak pressure-distance curves for moderately large distances are presented in a series of graphs, Figs. 1 to 7. Each graph gives a family of peak pressure-distance curves for a fixed value of the parameter Q_1 , plotted as $\log pR(\rho_e/W)^{1/3}$ versus $\log R(\rho_e/W)^{1/3}$. These graphs are designed to aid in the determination of the parameters from an experimental peak pressure-distance curve in a manner to be described in the following.

^{2/} Note that in the tables p is expressed in pounds per square inch, while in the equations p was a dimensionless quantity expressed in units of ρ_0 .

The family of shock-wave energy-distance curves is tabulated in Table II, the entries of which are $\rho_e \xi$ with the reduced distance defined in the foregoing as argument. The units of ξ are calories per gram of explosive.

The family of positive impulse-distance curves was constructed with the aid of Eqs. (3), and it is tabulated in Table III. Here, the function $10^3 IR(\rho_e/W)^{2/3}$ is listed with the reduced distance as argument. The units of I are pound second per square inch. Portions of these curves for moderately large distances are presented in the series of graphs, Figs. 8 to 14. These graphs are analogous to those for the peak pressure, with the function $10^3 IR(\rho_e/W)^{2/3}$ being plotted against $\log R(\rho_e/W)^{1/3}$ for fixed values of the parameter Q_1 . They will be useful in the determination of the initial parameters from experimental values of the positive impulse.

3. Determination of the initial parameters from experimental data

The graphs, Figs. 1 to 14 are designed to aid in the determination of the parameters of those members of the families of peak-pressure and positive-impulse curves that give the best fit to a particular set of experimental data. For this purpose, the experimental data may be plotted to the correct scale on tracing cloth and compared with the theoretical values by superimposing the tracing on the published graphs. Unless the data are of high accuracy, this procedure will not lead to a unique determination of the parameters but to the selection of several pairs of values of the parameters between which a choice could not easily be made by visual methods. The method of least squares may then be used to narrow the choice of parameters. One computes the mean of the squares of the weighted deviations of the individual experimental values of the peak pressure and positive impulse from the theoretical values given by the curves selected by visual matching, employing the reciprocal of the root mean square deviations of the experimental points at a given distance from their mean as the weight factor at that distance. One then selects the parameter set yielding the smallest value of this quantity for both peak pressure and impulse.^{3/}

^{3/} See E. T. Whittaker and G. Robinson, The calculus of observations, 3rd edition (Blackie and Son, 1940), pp. 182, 221.

CONFIDENTIAL

We have employed the method outlined to obtain estimates of the properties of the blast wave of TNT. The results are presented in Part III of this report. They will serve to illustrate the method of curve fitting which is proposed.

It should be noted that results of high accuracy can not be obtained in this manner. Thus the procedure is numerically unfavorable for the prediction of effects close to the charge. It is believed that thermodynamic estimates of the initial pressure, on which calculations are now in progress, will greatly increase the accuracy with which the parameters may be fixed.

III. BLAST-WAVE CURVES FOR CAST TNT

The peak pressure, shock-wave energy, and positive impulse of the blast wave produced by cast TNT have been estimated, employing the procedure described in Part I for the determination of the initial parameters from experimental peak pressures measured at large distances from the charge. We have chosen peak pressures recently determined by the shock-velocity method^{4/} in preference to those determined by piezoelectric-gauge measurements because of present gauge-calibration difficulties which may necessitate revision of the results obtained by the latter method.^{5/} The shock-velocity method does not lead simultaneously to measurements of the positive impulse, and therefore the initial parameters were determined from peak pressures alone. The experimental measurements were made at the Underwater Explosives Research Laboratory.^{6/}

The experimental values of the peak pressure are listed in Table IV. As a result of the visual curve-fitting, the three pairs of initial parameters listed in Table V were selected. Since standard deviations for the experimental points were not determined, each deviation of experimental peak pressure from the corresponding theoretical value was given unit weight in computing the mean-square deviation of the experimental values from the theoretical values. From a consideration of these mean-square deviations, listed in Table V, the parameter set $p_1 = 550$, $Q_1 = 450$

Table IV. Experimental peak pressures for TNT.

$R/W^{1/3}$	p (lb/in ²)
6.56	17.5
7.90	11.6
15.0	3.65

Table V. Mean-square deviations of experimental peak pressures from selected members of the family of theoretical peak-pressure curves.

Q_1	p_1	Δp^2
350	800	0.224
400	650	.208
450	550	.114

was chosen as affording the best representation of the experimental points. The individual deviations of the selected theoretical points from the corresponding experimental points is shown in Table VI.

Table VI. Comparison of experimental peak pressures for TNT with
the theoretical peak pressure-distance curve
for which $Q_1 = 450$, $p_1 = 550$.

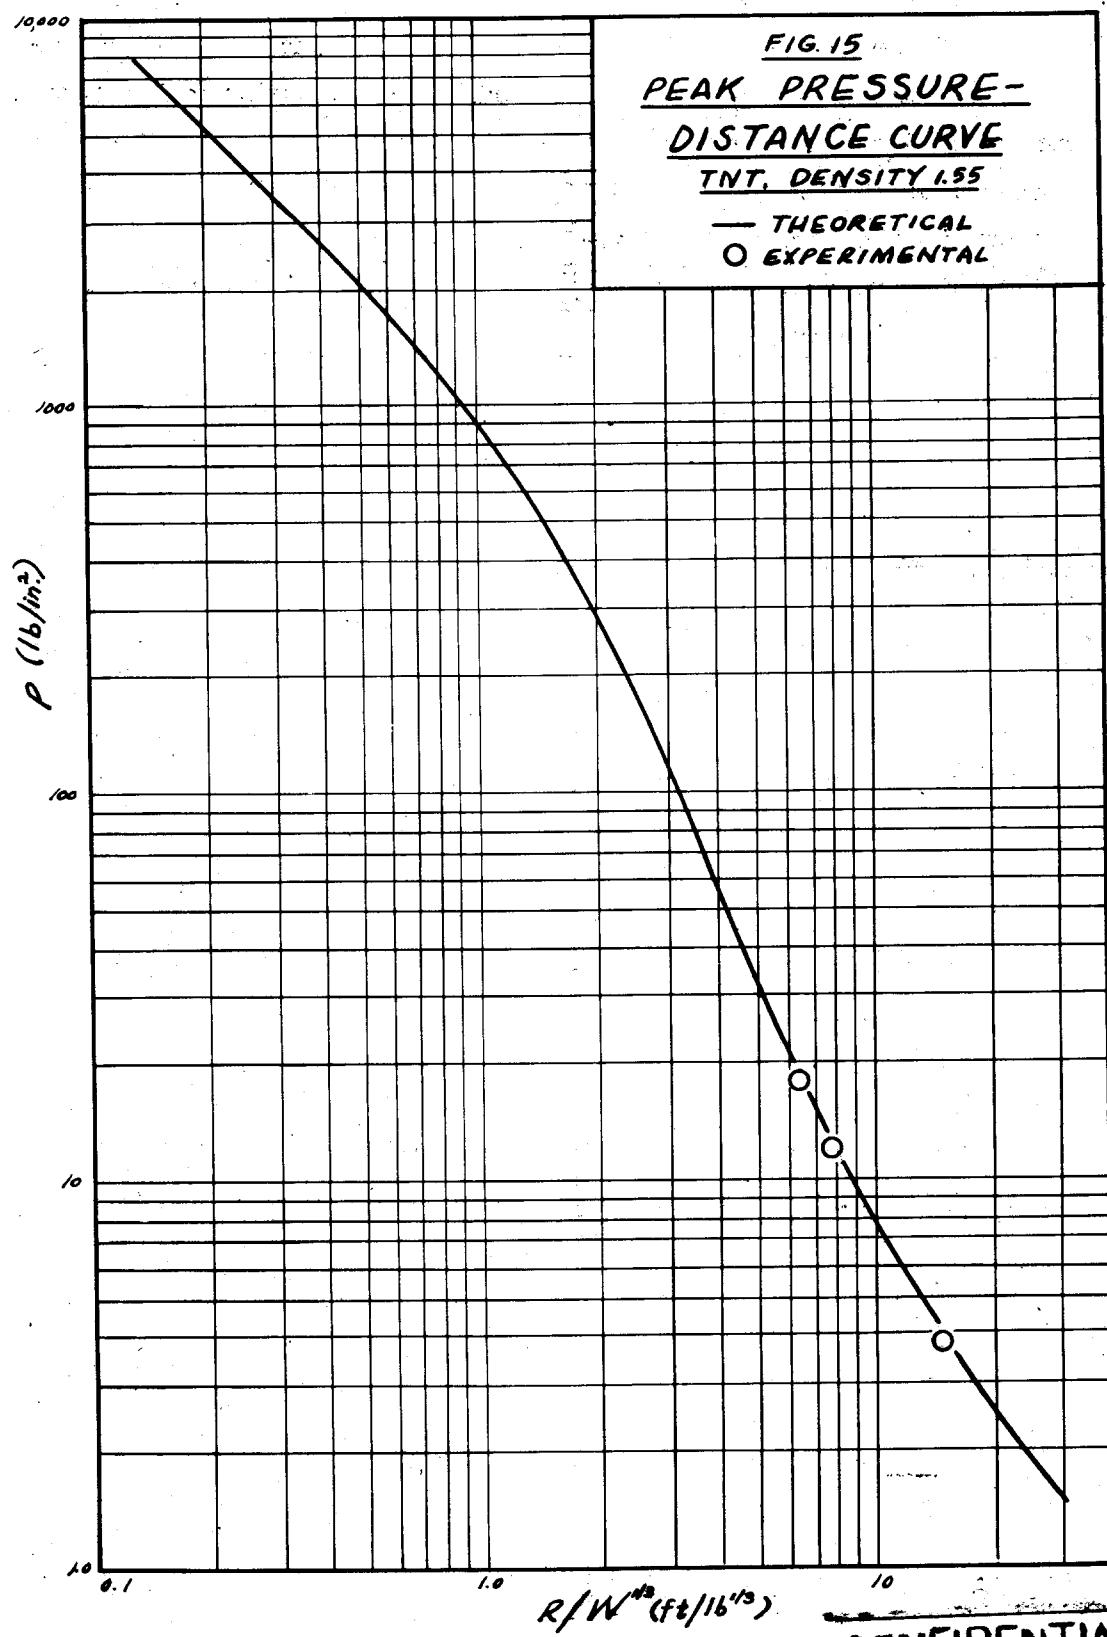

$R/W^{1/3}$ (ft/lb ^{1/3})	p (lb/in ²)		Deviation (percent)
	Experimental	($Q_1 = 450$, $p_1 = 550$)	
6.56	17.5	17.0	2.9
7.90	11.6	11.6	0.0
15.0	3.65	3.83	4.7
		Average 2.5	

The complete peak pressure-distance, energy-distance, and positive impulse-distance curves for cast TNT were constructed from Tables I to III, employing the initial parameters as determined above. These results are listed in Table VII, and the peak pressure-distance curve is shown in Fig. 15. Interpolation of the tabulated quantities to rounded values of $R/W^{1/3}$ was performed graphically.

The initial pressure for TNT of 7960 lb/in² is lower than the values previously estimated^{1/} of 10400 lb/in² for Pentolite and 8076 lb/in² for Torpex 2. The initial shock-wave energy of 1.17 kcal/gm for TNT is to be compared with the values 1.45 kcal/gm for Pentolite and 1.26 kcal/gm for Torpex 2. The heat of explosion of TNT has been estimated to be 1.06 kcal/gm. The higher value of the initial shock-wave energy is evidence for afterburning of the products of explosion with atmospheric oxygen, although the amount of energy contributed by such afterburning is difficult to estimate since a part of the energy of the explosion products will contribute to secondary shocks. As shown in the earlier report,^{1/} the tabulated values of the properties of the blast wave represent lower limits to the actual values during such time as afterburning is effective.

ABSTRACT:						
<p>Two-parameter families of curves for blast waves from explosive sources in air are presented. Determination of parallels is made from experimental values of peak pressure and positive impulse over limited range of distance. Peak pressure, shock wave energy, and positive impulse of blast wave produced by cast TNT are given. High value of shock wave energy is evident for afterburning of product of explosion with atmospheric oxygen.</p>
